explain accept4(3)

explain_accept4(3)

NAME

explain_accept4 - explain accept4(2) errors

SYNOPSIS

#include libexplain/accept4.h>

const char *explain_accept4(int fildes, struct sockaddr *sock_addr, socklen_t *sock_addr_size, int flags);

const char *explain_errno_accept4(int errnum, int fildes, struct sockaddr *sock_addr, socklen_t *sock_addr_size, int flags);

void explain_message_accept4(char *message, int message_size, int fildes, struct sockaddr *sock_addr, socklen_t *sock_addr_size, int flags);

void explain_message_errno_accept4(char *message, int message_size, int errnum, int fildes, struct sockaddr *sock_addr, socklen_t *sock_addr_size, int flags);

DESCRIPTION

These functions may be used to obtain explanations for errors returned by the accept4(2) system call.

explain_accept4

const char *explain_accept4(int fildes, struct sockaddr *sock_addr, socklen_t *sock_addr_size, int flags);

The **explain_accept4** function is used to obtain an explanation of an error returned by the *accept4*(2) system call. The least the message will contain is the value of strerror(errno), but usually it will do much better, and indicate the underlying cause in more detail.

The errno global variable will be used to obtain the error value to be decoded.

fildes The original fildes, exactly as passed to the accept4(2) system call.

sock_addr

The original sock_addr, exactly as passed to the *accept4*(2) system call.

sock_addr_size

The original sock_addr_size, exactly as passed to the *accept4*(2) system call.

flags The original flags, exactly as passed to the accept4(2) system call.

Returns: The message explaining the error. This message buffer is shared by all libexplain functions which do not supply a buffer in their argument list. This will be overwritten by the next call to any libexplain function which shares this buffer, including other threads.

Note: This function is **not** thread safe, because it shares a return buffer across all threads, and many other functions in this library.

Example: This function is intended to be used in a fashion similar to the following example:

```
int result = accept4(fildes, sock_addr, sock_addr_size, flags);
if (result < 0)
{
    fprintf(stderr, "%s\n", explain_accept4(fildes, sock_addr,
         sock_addr_size, flags));
    exit(EXIT_FAILURE);
}</pre>
```

The above code example is available pre-packaged as the *explain_accept4_or_die*(3) function.

explain errno accept4

const char *explain_errno_accept4(int errnum, int fildes, struct sockaddr *sock_addr, socklen_t *sock addr size, int flags);

The **explain_errno_accept4** function is used to obtain an explanation of an error returned by the *accept4*(2) system call. The least the message will contain is the value of strerror(errno), but usually it will do much better, and indicate the underlying cause in more detail.

The error value to be decoded, usually obtained from the *errno* global variable just before this function is called. This is necessary if you need to call **any** code between the system call to be explained and this function, because many libc functions will alter the value of *errno*.

fildes The original fildes, exactly as passed to the accept4(2) system call.

explain accept4(3) explain accept4(3)

sock_addr

The original sock_addr, exactly as passed to the accept4(2) system call.

sock_addr_size

The original sock_addr_size, exactly as passed to the *accept4*(2) system call.

flags The original flags, exactly as passed to the accept4(2) system call.

Returns: The message explaining the error. This message buffer is shared by all libexplain functions which do not supply a buffer in their argument list. This will be overwritten by the next call to any libexplain function which shares this buffer, including other threads.

Note: This function is **not** thread safe, because it shares a return buffer across all threads, and many other functions in this library.

Example: This function is intended to be used in a fashion similar to the following example:

```
int result = accept4(fildes, sock_addr, sock_addr_size, flags);
if (result < 0)
{
   int err = errno;
   fprintf(stderr, "%s\n", explain_errno_accept4(err, fildes, sock_addr, sock_addr_size, flags));
   exit(EXIT_FAILURE);
}</pre>
```

The above code example is available pre-packaged as the *explain_accept4_or_die*(3) function.

explain_message_accept4

void explain_message_accept4(char *message, int message_size, int fildes, struct sockaddr *sock_addr, socklen_t *sock_addr_size, int flags);

The **explain_message_accept4** function is used to obtain an explanation of an error returned by the *accept4*(2) system call. The least the message will contain is the value of strerror(errno), but usually it will do much better, and indicate the underlying cause in more detail.

The errno global variable will be used to obtain the error value to be decoded.

message The location in which to store the returned message. If a suitable message return buffer is supplied, this function is thread safe.

message_size

The size in bytes of the location in which to store the returned message.

fildes The original fildes, exactly as passed to the accept4(2) system call.

sock_addr

The original sock_addr, exactly as passed to the *accept4*(2) system call.

sock addr size

The original sock_addr_size, exactly as passed to the *accept4*(2) system call.

flags The original flags, exactly as passed to the accept4(2) system call.

Example: This function is intended to be used in a fashion similar to the following example:

```
int result = accept4(fildes, sock_addr, sock_addr_size, flags);
if (result < 0)
{
    char message[3000];
    explain_message_accept4(message, sizeof(message), fildes,
    sock_addr, sock_addr_size, flags);
    fprintf(stderr, "%s\n", message);
    exit(EXIT_FAILURE);
}</pre>
```

The above code example is available pre-packaged as the explain_accept4_or_die(3) function.

explain_message_errno_accept4

void explain_message_errno_accept4(char *message, int message_size, int errnum, int fildes, struct sockaddr *sock_addr, socklen_t *sock_addr_size, int flags);

```
explain_accept4(3)
```

The **explain_message_errno_accept4** function is used to obtain an explanation of an error returned by the *accept4*(2) system call. The least the message will contain is the value of strerror(errno), but usually it will do much better, and indicate the underlying cause in more detail.

explain accept4(3)

message The location in which to store the returned message. If a suitable message return buffer is supplied, this function is thread safe.

message size

The size in bytes of the location in which to store the returned message.

errnum The error value to be decoded, usually obtained from the error global variable just before this function is called. This is necessary if you need to call **any** code between the system call to be explained and this function, because many libc functions will alter the value of error.

fildes The original fildes, exactly as passed to the accept4(2) system call.

sock_addr

The original sock addr, exactly as passed to the *accept4*(2) system call.

sock_addr_size

The original sock_addr_size, exactly as passed to the *accept4*(2) system call.

flags The original flags, exactly as passed to the accept4(2) system call.

Example: This function is intended to be used in a fashion similar to the following example:

```
int result = accept4(fildes, sock_addr, sock_addr_size, flags);
if (result < 0)
{
    int err = errno;
    char message[3000];
    explain_message_errno_accept4(message, sizeof(message),
    err, fildes, sock_addr, sock_addr_size, flags);
    fprintf(stderr, "%s\n", message);
    exit(EXIT_FAILURE);
}</pre>
```

The above code example is available pre-packaged as the explain_accept4_or_die(3) function.
