LIBRARY

Mifare card manipulation library (libfreefare, -lfreefare)

SYNOPSIS

```

#include <freefare.h>

int
mifare_desfire_connect(MifareTag tag);

int
mifare_desfire_disconnect(MifareTag tag);

int
mifare_desfire_authenticate(MifareTag tag, uint8_t key_no,
    MifareDESFireKey key);

int
mifare_desfire_authenticate_aes(MifareTag tag, uint8_t key_no,
    MifareDESFireKey key);

```

```
int
mifare_desfire_authenticate_iso(MifareTag tag, uint8_t key_no,
    MifareDESFireKey key);

int
mifare_desfire_change_key_settings(MifareTag tag, uint8_t settings);

int
mifare_desfire_get_key_settings(MifareTag tag, uint8_t *settings,
    uint8_t *max_keys);

int
mifare_desfire_change_key(MifareTag tag, uint8_t key_no,
    MifareDESFireKey new_key, MifareDESFireKey old_key);

int
mifare_desfire_get_key_version(MifareTag tag, uint8_t key_no,
    uint8_t *version);

int
mifare_desfire_create_application(MifareTag tag, MifareDESFireAID aid,
    uint8_t settings, uint8_t key_no);

int
mifare_desfire_create_application_aes(MifareTag tag,
    MifareDESFireAID aid, uint8_t settings, uint8_t key_no);

int
mifare_desfire_create_application_3k3des(MifareTag tag,
    MifareDESFireAID aid, uint8_t settings, uint8_t key_no);

```

DESCRIPTION

The `mifare_desfire_*`() functions allows management of Mifare DESFire tags.

Card-level operations

The `mifare_desfire_connect()` and `mifare_desfire_disconnect()` functions activates and deactivates the provided `tag`. All `mifare_desfire_*`() functions that operates on a `tag` require it to be on activated.

After activation, the selected application is the master application. It is possible to select another application using the `mifare_desfire_select_application()` function (see bellow).

The `mifare_desfire_get_version()` function retrieve various information about the provided `tag`, including UID, batch number, production date, and hardware and software information. Refer to the `freemem.h` header file for details about the `version_info` field.

The `mifare_desfire_free_mem()` functions returns the *size* of the free memory on the PICC (in bytes).

The `mifare_desfire_set_configuration()` function can be used to deactivate the format function when setting `disable_format` to a value different from 0, or swicth the card to use random UDI setting `enable_random_uid` to a non-zero value.

The `mifare_desfire_set_default_key` function sets the `key` argument as the default key for new applications.

The `mifare_desfire_set_ats` function replace the ATS bytes returned by PICC when it is selected.

The `mifare_desfire_get_card_uid` function can be used with a PICC configured for using random UID to retrieve the original UID of the target.

The `mifare_desfire_format_picc()` function resets `tag` to factory defaults. For this function to work, a previous authentication with the card master key is required.

Application-level operations

The `mifare_desfire_select_application()` function makes the application identified by `aid` the active one. Further file operations will be performed in the context of this application. After a call to `mifare_desfire_connect`, the default application is the card master application. It can be selected again calling the `mifare_desfire_select_application()` function either with an `aid` with all its fields set to 0, or by providing the NULL `aid`.

The `mifare_desfire_authenticate()` function performs an authentication using the key number `key_no` on the card and the `key` (3)DES key on `tag`.

The `mifare_desfire_authenticate_aes()` function performs an authentication using an AES `key`.

The `mifare_desfire_authenticate_iso()` function performs an ISO authentication using either a 3DES or a 3K3DES `key`.

The `mifare_desfire_get_key_settings()` function, returns the `settings` and the number of keys `max_keys` of the selected application.

The `mifare_desfire_change_key_settings()` function changes the selected application settings to `settings`. The application number of keys cannot be changed after the application has been created.

The `mifare_desfire_change_key()` changes the key `key_no` from `old_key` to `new_key` on `tag`. Depending on the application settings, a previous authentication with the same key or another key may be required.

The `mifare_desfire_get_key_version()` function retrieves the `version` of the key with number `key_no` of the selected application.

The `mifare_desfire_create_application()` function, creates an application with AID `aid`, the `settings` key settings and `key_no` authentication keys. Authentication keys are set to 0 after creation.

The `mifare_desfire_create_application_3k3des()` and `mifare_desfire_create_application_aes()` functions acts as the `mifare_desfire_create_application()` function except that the whole application is configured to use 3K3DES or AES keys. It is possible to achieve the same result using the `mifare_desfire_create_application()` function and ORing the `key_no` argument with `APPLICATION_CRYPT_3K3DES` or `APPLICATION_CRYPT_AES` respectively.

The `mifare_desfire_create_application_iso()` acts as the `mifare_desfire_create_application()` function but allows one to specify if the created files within the application shall have an ISO file identifier setting `want_iso_file_identifiers` to a non-NULL value, a DF can be provided using `iso_file_id`, as long as an optional file name `iso_file_name` of length `iso_file_name_len` (in bytes).

The `mifare_desfire_create_application_3k3des_iso()` and `mifare_desfire_create_application_aes_iso()` function acts as the regular `mifare_desfire_create_application_3k3des()` and `mifare_desfire_create_application_aes()` functions, providing the same extensions ISO parameters of `mifare_desfire_create_application_iso()`.

The `mifare_desfire_delete_application()` deletes the application identified by AID *aid*.

The `mifare_desfire_get_application_ids()` function returns a list of all applications of the card. The *aids* array has to be freed after usage calling `mifare_desfire_free_application_ids()`.

The `mifare_desfire_get_df_names()` retrieves the list of DF *dfs* from *tag* and set *count* to the number of items in the allocated array. Memory has to be freed by the user using `free(3)`.

File-level operations

The `mifare_desfire_get_file_ids()` function returns the list of *count* files in the selected application as *files*. The memory allocated for *files* has to be reclaimed using `free(3)`.

The `mifare_desfire_get_iso_file_ids()` function returns the list of *count* file ISO identifiers as *files*. The memory allocated for *files* has to be reclaimed using `free(3)`.

The `mifare_desfire_get_file_settings()` function retrieves the *settings* of the file *file_no* of the selected application of *tag*.

The `mifare_desfire_change_file_settings()` function change the *communication_settings* and *access_rights* of the file *file_no* of the selected application of *tag*.

The `mifare_desfire_create_*`() family of functions create a new file *file_no* with the provided *communication_settings* and *access_rights* on *tag*.

`mifare_desfire_create_std_data_file()`
creates a standard data file of size *file_size*.

`mifare_desfire_create_backup_data_file()`
creates a backup data file of size *file_size*.

`mifare_desfire_create_value_file()`
creates a value file of value *value* constrained in the range *lower_limit* *upper_limit*, and with the *limited_credit_enable* settings.

`mifare_desfire_create_linear_record_file()`
creates a linear record file that can hold *max_number_of_records* records of size *record_size*.

`mifare_desfire_create_cyclic_record_file()`
creates a cyclic record file that can hold *max_number_of_records* records of size *record_size*.

The `mifare_desfire_create*_iso()` family of functions acts as the functions without the *_iso* suffix but provide an additional argument *iso_file_id*.

The `mifare_desfire_delete_file()` removes the file *file_no* from the selected application of *tag*.

Data-level operations

The `mifare_desfire_read_data()` function reads *length* bytes of data from offset *offset* of the file *file_no* and copies it to *data*. If *length* is set to 0, the file is read to end. The function returns the number of bytes read.

The `mifare_desfire_write_data()` function writes *length* bytes of data from offset *offset* of the file *file_no* and copies it to *data*. The function returns the number of bytes written.

The `mifare_desfire_get_value()` reads the *value* of the file *file_no* of the selected application.

The `mifare_desfire_credit()` function adds *amount* to the value of the file *file_no* of the selected application.

The `mifare_desfire_debit()` function subtracts *amount* to the value of the file *file_no* of the selected application.

to the value of the file *file_no* of the selected application.

The `mifare_desfire_limited_credit()` function adds *amount* to the value of the file *file_no* of the selected application.

The `mifare_desfire_write_record()` function writes *length* records starting at record *offset* of *data* in the file *file_no* and returns the number of bytes written.

The `mifare_desfire_read_records()` function reads *length* records starting at record *offset* from the file *file_no* and copy them to *data*, returning the number of bytes read.

The `mifare_desfire_clear_record_file()` function erase all records from the file *file_no* of the selected application.

The `mifare_desfire_commit_transaction()` validates the set of pending changes on the *tag*, while the `mifare_desfire_abort_transaction()` rollbacks the changes.

All data-manipulation functions that read data from and write data to files come with an `*_ex()` variant (e.g. `mifare_desfire_read_data_ex()`) which accepts an extra parameter *cs* that defines the communication settings to use. If not provided, the library will try to read-out this value from the file's configuration. Because reading this information may be denied, the `*_ex()` variant of functions still allows using the library for advanced usage.

RETURN VALUES

Unless stated otherwise, all other functions return a value greater than or equal to 0 on success or -1 on failure.
